A First Result in Complex Approximation

By: Alexander Kroitor (University of Waterloo)

Select an interval $[a, b]$ in \mathbb{R} and $\epsilon > 0$. A well-known theorem by Weierstrass [1], proven in 1885, states that for any function $f(x)$ from \mathbb{R} to \mathbb{R} continuous at each point in $[a, b]$ there exists a polynomial with real coefficients $P(x)$ (depending on $[a, b]$, ϵ , and f) that uniformly approximates f on the interval $[a, b]$ up to error ϵ . That is, $|f(x) - P(x)| < \epsilon$ for all $x \in [a, b]$.

It is natural to look at this result and think of how it can be generalized. There are multiple directions to try, and it turns out that moving to complex functions rather than real functions yields some beautiful results. This motivates the rich topic of **complex approximation**, the field of approximating functions from \mathbb{C} to \mathbb{C} . In order to delve in properly, we recall from complex analysis that a function f is **analytic** at a point z_0 if f can be expanded as a power series centered at z_0 (we can think of this as f being “nice” at z_0).

In 1951 Mergelyan proved the following powerful result [2]. First, select a compact set K in \mathbb{C} such that the complement of K is connected, that is we cannot write the complement of K as a disjoint union of two other non-empty open sets. Then given a function $f(z)$ from \mathbb{C} to \mathbb{C} that is continuous at each point in K , and analytic at each point in the interior of K , there exists a polynomial with complex coefficients $P(z)$ (once again depending on K , ϵ , and f) that uniformly

approximates f on K up to error ϵ .

The requirement that f be analytic may look restrictive, but the fact that the analyticity requirement is only for the interior of K renders this quite benign. We can achieve powerful results by constraining ourselves to sets that have no interior. Recall that given a complex number z in \mathbb{C} we can split it into its real and imaginary parts as $z = \text{Re}(z) + i \text{Im}(z)$, where $\text{Re}(z)$ and $\text{Im}(z)$ are real numbers. We can do the same to functions: given a function $f(z)$ we can split it into its real and complex parts $f(z) = \text{Re} f(z) + i \text{Im} f(z)$ where $\text{Re} f$ and $\text{Im} f$ are functions from \mathbb{C} to \mathbb{R} . It is straightforward to see that if P is a polynomial with complex coefficients, then $\text{Re} P$ is also a polynomial with real coefficients.

Mergelyan’s Theorem has Weierstrass’s Theorem as a corollary. Pick an interval $[a, b]$ in \mathbb{R} and a function $f(x)$ that is continuous on $[a, b]$, and define

$$K := \{z \in \mathbb{C} \mid \text{Re}(z) \in [a, b], \text{Im}(z) = 0\},$$
$$g(z) := f(\text{Re}(z)) \in \mathbb{R}.$$

Since g is continuous, and K has no interior, Mergelyan’s theorem gives us a complex polynomial $P(z)$ such that $|g(z) - P(z)| < \epsilon$ on K . [Continued on page 2]

When not grading and giving tutorials, I occasionally squeeze in time for math. ◀

Preamble

By: Courtney Allen (University of Guelph)

It's a common question heard in math classes the world over: "Why do I have to show my work?" It's a good question: if the answer's right, then why does it matter how I got it? While "showing you work" often seems like busy-work, if you've taken even one course in so-called "advanced" mathematics, you know the truth. The *only* thing that matters is your work.

If you've known me in real life for a sufficiently long period of time, you've probably heard me say, in an exasperated tone of voice, "Math is about communication!" because, well... it is. Nobody cares that the answer is 42 if you can't explain how you got there. Mathematics is a tool that we use to describe the world around us.

It's for that reason that I'm so happy to be bringing back *Notes from the Margin* after its extended hiatus. Providing an outlet for mathematics students to communicate and discuss mathematics is integral to a well-rounded mathematical education, and it's a privilege to have collaborated with such brilliant contributors on this edition.

In this issue we take a dive into complex analysis, linear algebra, and take a look at an important figure in the history of mathematics. We also celebrate the work of the winners of the Summer 2022 and Winter 2022 AARMS-CMS Student Poster Session.

If you want to see your work in *The Margin*, or if you have questions or comments about the articles in this issue, contact the editor at student-editor@cms.math.ca.

Courtney Allen
Acting Editor-In-Chief

What does it take to be a mathematician? [...] It does not take brilliance, but love of a great game!

- Karen Keskulla Uhlenbeck

[Continued from cover page]

Since $|a + ib| \geq |a|$, we have that, for z in K ,

$$\begin{aligned} \epsilon &> |g(z) - P(z)| \\ &= |f(\operatorname{Re}(z)) - \operatorname{Re} P(z) - i \operatorname{Im} P(z)| \\ &= |f(z) - \operatorname{Re} P(z) - i \operatorname{Im} P(z)| \\ &\geq |f(z) - P(z)|, \end{aligned}$$

and so on K (and thus on our interval $[a, b]$) we have found a real polynomial $\operatorname{Re} P$ that uniformly approximates f up to error ϵ .

This is only a small result in complex approximation, and still has the requirement that the complement of K is connected. Removing this requirement leads to approximations with rational functions instead of polynomials. Further generalization lead to an elegant proof of the beautiful **Birkhoff's Universality Theorem**, but that would be a theorem for another article.

L'enveloppe spectrale des matrices bistochastiques: Une étude de cas du comportement étrange des petits nombres

By: Ludovick Bouthat (Université Laval)

Une matrice carrée est dite *stochastique* si elle est non-négative et si la somme des coefficients de chaque ligne est égale à 1. De même, une matrice carrée est dite *bistochastique* si elle est non-négative et si la somme des coefficients de chaque ligne et de chaque colonne est égale à 1. De manière équivalente, une matrice est bistochastique si la matrice et sa transposée sont toutes deux stochastiques. Ici, nous dénotons l'ensemble des matrices $n \times n$ bistochastiques par \mathcal{D}_n .

En 1938, lors d'une conférence sur les chaînes de Markov organisée sous l'égide de la Société mathématique de Moscou, le célèbre mathématicien Andreï Kolmogorov définit Ω_n comme l'ensemble de toutes les valeurs propres de toutes les matrices stochastiques $n \times n$ et pose le problème de la détermination de cette région. Treize ans plus tard, en 1951, F. Karpelevič [1] obtenu finalement une description complète de Ω_n pour tout $n \geq 1$.

Figure 1: Ω_4

Figure 2: Ω_5

Les régions Ω_4 et Ω_5 et les polygones réguliers capturant les extrémités.

Une question analogue, proposée par L. Mirsky en 1963 [2], consiste à déterminer la région ω_n de toutes les valeurs propres de toutes les matrices $n \times n$ bistochastiques, c'est-à-dire $\omega_n := \{\lambda \in \mathbb{C} : \lambda \in \sigma(D), D \in \mathcal{D}_n\}$. Puisque toute matrice bistochastique est également stochastique, nous avons clairement $\omega_n \subseteq \Omega_n$. De plus, posons $\Pi_n = \text{Conv}\{e^{2\pi i/n}, e^{2 \times 2\pi i/n}, \dots, e^{n \times 2\pi i/n}\}$, soit l'enveloppe convexe fermée des n^e racines de l'unité, qui est le n -gone régulier dans le disque ancré au point 1. Nous avons le résultat suivant, dû à Perfect et Mirsky [2].

Théorème. $\Pi_1 \cup \Pi_2 \cup \dots \cup \Pi_n \subseteq \omega_n$.

Avec des méthodes relativement simples, on peut montrer que

$$\omega_2 = \Pi_1 \cup \Pi_2 = [-1, 1] \quad \text{et} \quad \omega_3 = \Pi_1 \cup \Pi_2 \cup \Pi_3.$$

Conjecture (Perfect–Mirsky). $\omega_n = \bigcup_{k=1}^n \Pi_k$.

En 2006, Mashreghi et Rivard [3] ont identifié la matrice bistochastique

$$S_t := \begin{bmatrix} 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & t & 0 & 1-t \\ 0 & t & 1-t & 0 & 0 \\ 0 & 1-t & 0 & 0 & t \\ 1 & 0 & 0 & 0 & 0 \end{bmatrix}, \quad (0 \leq t \leq 1)$$

et ont observé que pour au moins $t \in [0.49, 0.51]$, S_t admet une valeur propre en dehors de la région conjecturée $\bigcup_{k=1}^5 \Pi_k$. Ainsi, en laissant varier t et en calculant la valeur propre exceptionnelle de S_t , on obtient une courbe qui se situe partiellement en dehors de la région de Perfect–Mirsky (en rouge dans Figures 3 and 4).

Figure 3: La région ω_3 .

Figure 4: La région ω_4 .

Cependant, l'histoire ne s'arrête pas là puisqu'en 2015, Levick, Pereira et Kribs [4] ont montré que la conjecture est également vraie pour $n = 4$.

Figure 5: La région de Perfect–Mirsky $\bigcup_{k=1}^5 \Pi_k$ et la courbe exceptionnelle de Mashreghi–Rivard.

Figure 6: Gros plan sur la courbe exceptionnelle autour de $[-0.35, -0.2] \times [0.7, 0.85]$.

En ce qui concerne $n \geq 6$, le statut de la conjecture demeure en suspend. Cependant, Harlev, Johnson et Lim [5] ont récemment approché le problème numériquement. En se basant sur les travaux de Rivard et Mashreghi ainsi que sur leurs propres recherches, ils ont examiné les valeurs propres obtenues par des matrices bistochastiques qui peuvent être écrites comme une combinaison convexe d'au plus deux matrices de permutation pour $n \leq 11$ (comme c'est le cas pour S_t). Ils ont observés que pour chaque cas sauf $n = 5$, toutes les valeurs propres se trouvent dans $\bigcup_{k=1}^n \Pi_k$. Cela les a motivés à proposer la conjecture suivante.

Conjecture (Harlev–Johnson–Lim).
 $\omega_n = \bigcup_{k=1}^n \Pi_k$ pour $n \geq 1$, *sauf pour* $n = 5$.

Aussi troublante soit-elle, cette conjecture semble être la plus convaincante à ce jour, car elle est étayée par des calculs numériques et des propriétés algébriques de \mathcal{D}_n . Espérons qu'une nouvelle idée nous permettra de résoudre ce mystérieux problème. En attendant, nous concluons par la question ouverte suivante :

Question ouverte. *Quelle est la région ω_n pour $n \geq 5$? En particulier, peut-on caractériser la région ω_5 ?* ◀

Ada Lovelace: The Woman Who Saw the Future

By: Courtney Allen (University of Guelph)

In 1843, an English translation of a French article was published in Taylor’s Scientific Memoirs [1]. The article, originally written by Luigi Menabrea, outlined the workings of a hypothetical machine known as Babbage’s Analytical Engine, an early programmable computer. It was wildly influential, not for the article itself, but for the notes made by the translator, a young woman by the name of Augusta Ada King, the Countess of Lovelace.

Ada Lovelace, as she is more commonly known, was the only legitimate child of Lord Byron, born in England on 10 December 1815. After her parents separation, her mother, Lady Byron, encouraged her to pursue the sciences. Since the sciences were then thought to be the province of men, Lovelace gained her education by reading textbooks and corresponding with some of the greatest mathematical minds of the time, one of whom was Charles Babbage [2].

Seeing her interest in his proposed Analytical Engine, Babbage encouraged Lovelace to read and translate the aforementioned paper by Luigi Menabrea [3]. But Lovelace did more than that, she saw the potential of the Engine in a way that no one had before. Her notes were longer than the article itself, and contain the first computer program, a table designed for the Engine that

would compute the Bernoulli numbers [2]. More importantly, she saw the true power of the Analytical Engine, theorizing that it could be used to perform complicated tasks such as composing music [2]. Almost 100 years after her death from uterine cancer at age 36, her work continued to influence the inventors of the first modern computers, such as Alan Turing [3].

At a time when women’s mathematical aptitude was often dismissed, Ada Lovelace saw the possibilities of a machine that did not yet even exist

Almost Periodic Equidistributed Functions

- Yihan Zhu (University of Windsor)

ALMOST PERIODIC EQUIDISTRIBUTED FUNCTIONS
 Yihan Zhu
 University of Windsor

Background

There are plenty of periodic motions in our life. However, a linear combination of two or more periodic motions need not be periodic any longer. Almost periodic functions are more general than periodic functions. Therefore, the class of almost periodic functions forms a more suitable object of study from a structural point of view. Equidistribution, which is also known as uniform distribution, is an important concept in many areas including number theory, ergodic theory, probability and theoretical computer science. The classical theory of equidistribution of sequences was initiated by Weyl following earlier works by Bohl and Siegel. The formal definition of equidistribution mod 1 of sequences was given initially by Weyl in 1916. A sequence $\{x_n\}$ of real numbers is equidistributed mod 1 if for every pair a, b of real numbers with $0 < a < b \leq 1$,

$$\lim_{N \rightarrow \infty} \frac{1}{N} \sum_{n=1}^N 1_{[a,b]}(\{x_n\}) = b - a \quad (1)$$

where $1_{[a,b]}$ is the characteristic function of the subinterval $[a, b]$ and $\{x_n\}$ is the fractional part of x_n . The study of equidistribution of sequences in compact topological spaces was initiated by Eckmann in 1943. The main idea of this research is generalizing the existing concept of equidistributed sequences to equidistributed functions by using the property of the invariant mean on almost periodic functions.

An Example

Consider the amenable group $G = (\mathbb{0}, \infty) \times \mathbb{R}$ with the multiplication $(x, y) \cdot (x', y') = (x + x', y + y')$, and a left Haar measure $\mu = dx dy / x^2$. A Følner sequence $\{K_n\}_{n \in \mathbb{N}}$ for G is given by the trapezoidal regions K_n defined by:

$$K_n = \{(x, y) \in \mathbb{R}^2 : 1/n \leq x \leq n, -nx \leq y \leq nx\}.$$

Now, let $\varphi: G \rightarrow \mathbb{C} \setminus \{0, \infty\}$, be the canonical quotient homomorphism, and $\psi: (\mathbb{0}, \infty) \rightarrow (\mathbb{0}, \infty)$ by any continuous homomorphism with dense range. Then $\varphi \circ \psi: G \rightarrow (\mathbb{0}, \infty)$ is a continuous homomorphism with dense range in $(\mathbb{0}, \infty)$, and therefore $\varphi \circ \psi$ is μ -equidistributed along $\{K_n\}_{n \in \mathbb{N}}$.

As an example, let $\psi(x) = x^\alpha$, where $\alpha > 0$ is fixed. Then $\varphi(x, y) = \psi \circ \varphi(x, y) = x^\alpha$, and hence by definition, for every $f \in AP(\mathbb{0}, \infty)$ we have

$$(M, f) = \lim_{n \rightarrow \infty} \frac{1}{\mu(K_n)} \int_{K_n} (f \circ \varphi)(x, y) d\mu = \lim_{n \rightarrow \infty} \frac{1}{\mu(K_n)} \int_{1/n}^{n\alpha} \int_{-nx}^{nx} f(x^\alpha) \frac{dy dx}{x^2} = \lim_{n \rightarrow \infty} \frac{1}{2n \log n} \int_{1/n}^{n\alpha} f(x^\alpha) \frac{dx}{x}.$$

Applications

Theorem 2: Let H be a topological group, $m \geq 1$, and $\varphi: \mathbb{N}^m \rightarrow H$ a function. Suppose that there exists some $1 \leq l \leq m$, such that for every $h \in \mathbb{N}$, the function

$$\mathbb{N}^m \rightarrow H, \quad n \mapsto \varphi(n_1, \dots, n_l, h, \dots, h, n_{l+1}, \dots, n_{l+m}) \quad (8)$$

is μ -equidistributed along the monotone cover $\{K_N\}_{N \in \mathbb{N}}$. Then for all $q \in \mathbb{N}^m$, and all $r \in \mathbb{Z}^m$ with $r_j \geq 0$ ($1 \leq j \leq m$), the function

$$\varphi: \mathbb{N}^m \rightarrow H, \quad n \mapsto \varphi(nq + r) \quad (9)$$

is μ -equidistributed along $\{K_N\}_{N \in \mathbb{N}}$.

Theorem 3: Let $m \geq 1$ and $\{K_N\}_{N \in \mathbb{N}}$ be the monotone cover. Let $\varphi(x_1, \dots, x_m)$ be a polynomial in m variables and with real coefficients that contains at least one nonconstant term with an irrational coefficient. Then for all integers $q_j \geq 1$, $r_j \geq 0$ ($j = 1, \dots, m$), the function

$$\varphi: \mathbb{N}^m \rightarrow \mathbb{T}, \quad (n_1, \dots, n_m) \mapsto \varphi^{2\pi i(n_1 q_1 + r_1, \dots, n_m q_m + r_m)} \quad (10)$$

is μ -equidistributed along $\{K_N\}_{N \in \mathbb{N}}$, where μ is the normalized Lebesgue measure on \mathbb{T} .

Remark: Theorem 2 is a generalization of Hawka's equidistribution result while Theorem 3 is a generalization of van der Corput's result.

Definitions

If X is a topological space, then a **Banach function algebra** on X is a subalgebra A of $C(X)$ (continuous bounded functions on X) that is a Banach algebra under a norm $\|\cdot\|$. By a **monotone compact cover** on a topological space \mathcal{C} we mean a net $\{K_\alpha\}_{\alpha \in I}$ of bounded subsets of \mathcal{C} such that (i) $S = \bigcup_{\alpha \in I} K_\alpha$ and (ii) $K_\alpha \subset K_\beta$ if $\alpha \leq \beta$.

Definition 1: Let S be a locally compact space equipped with a regular Borel measure λ and a monotone compact cover $\{K_\alpha\}_{\alpha \in I}$. Let H be a topological group and M the invariant mean on $AP(H)$. A continuous mapping $\varphi: S \rightarrow H$ is called **almost periodic equidistributed (a.p. equidistributed)** along $\{K_\alpha\}_{\alpha \in I}$ if for every $f \in A$:

$$(M, f) = \lim_{\alpha \in I} \frac{1}{\lambda(K_\alpha)} \int_{K_\alpha} f \circ \varphi d\lambda(x). \quad (2)$$

Remark: In particular, if $S = \mathbb{N}$ with the counting measure and the monotone compact cover $\{\mathbb{N}_N\}_{N \in \mathbb{N}}$, (2) could be interpreted as:

$$(M, f) = \lim_{N \rightarrow \infty} \frac{1}{N} \sum_{n=1}^N f(x_n), \quad f \in A. \quad (3)$$

which coincides with the definition of equidistribution of sequences. As a special case, we may consider the equidistribution of functions with respect to almost periodic means.

Definition 2: Let S be a locally compact space equipped with a regular Borel measure λ and a monotone compact cover $\{K_\alpha\}_{\alpha \in I}$. Let H be a topological group and M the invariant mean on $AP(H)$. A continuous mapping $\varphi: S \rightarrow H$ is called **almost periodic equidistributed (a.p. equidistributed)** along $\{K_\alpha\}_{\alpha \in I}$ if it is M -equidistributed along $\{K_\alpha\}_{\alpha \in I}$.

Main Result

Theorem 1 (Weyl's criterion): Let S be a locally compact space equipped with a regular Borel measure λ and a monotone compact cover $\{K_\alpha\}_{\alpha \in I}$. Let H be a topological group. Then a continuous mapping $\varphi: S \rightarrow H$ is μ -equidistributed along $\{K_\alpha\}_{\alpha \in I}$ if and only if

$$\lim_{\alpha \in I} \frac{1}{\lambda(K_\alpha)} \int_{K_\alpha} (\sigma_j \circ \varphi)(x) d\lambda(x) = 0, \quad (4)$$

for all nontrivial $\sigma \in \mathcal{V}_H$, $1 \leq j \leq d_\sigma$.

Proof of Theorem 1: First, suppose that φ is μ -equidistributed along $\{K_\alpha\}_{\alpha \in I}$, and let M be the almost periodic mean on $AP(H)$. Since $\sigma_j \in AP(H)$ ($1 \leq j \leq d_\sigma$), by Definition 2 we can write

$$(M, \sigma_j) = \lim_{\alpha \in I} \frac{1}{\lambda(K_\alpha)} \int_{K_\alpha} (\sigma_j \circ \varphi)(x) d\lambda(x) = 0. \quad (5)$$

Consider the inner product on $AP(H)$ defined by $(f, g) = M(f \bar{g})$, $f, g \in AP(H)$. By assumption $\sigma_j \notin \mathcal{V}_H$, and therefore we can use the orthogonality relation between coefficient functions of representations in \mathcal{V}_H to write

$$(M, \sigma_j) = (M, \sigma_j 1_H) = (\sigma_j 1_H, 1) = 0. \quad (6)$$

The identities (5) and (6) imply (4). Conversely, suppose that (4) holds. We need to show that

$$\lim_{\alpha \in I} \frac{1}{\lambda(K_\alpha)} \int_{K_\alpha} (f \circ \varphi)(x) d\lambda(x) = (M, f) \quad \text{for all } f \in AP(H). \quad (7)$$

Since M is a mean on $AP(H)$, we have $(M, 1_H) = 1$, and hence both sides of (7) are equal to 1 for $f = 1_H$. If $f = \sigma_j \circ \varphi$, $\sigma_j \in \mathcal{V}_H$, $1 \leq j \leq d_\sigma$, then (7) holds by (4) and (6). Thus (7) holds for all linear combinations of coefficient functions of representations in \mathcal{V}_H . Since such functions are uniformly dense in $AP(H)$, (7) follows by a 3-argument.

Further Questions

- We believe that our results for equidistribution of continuous functions with values in topological groups can be extended to continuous functions with values in topological semigroups.
- We will try to explore whether above results have any relationship with the ergodic theory, such as the mean ergodic theorem and so on.

Acknowledgements

I would like to express my special thanks of gratitude to my supervisor Dr. Mehdi S. Mosharraf for his patient and kind help in both this project and in my studies.

Analyzing Distance-Regular Graphs Arizing From Primitive Groups

- Alaina Parady and Abigail Rowsell (Memorial University of Newfoundland Grenfell Campus)

Analyzing Distance-Regular Graphs Arizing From Primitive Groups
 Alaina Parady, Abigail Rowsell
 Memorial University of Newfoundland Grenfell Campus

Introduction

A distance-regular graph is a regular, connected graph with degree k and diameter d , such that the following holds. The graph has intersection numbers

$$b_0 = k, b_1 = k-1, \dots, b_{d-1} = 1, c_0 = 0, c_1 = 1, \dots, c_{d-1} = k$$

such that for every pair of vertices x, y at distance i , we have

1. the number of vertices in $V_{i+1}(x)$ adjacent to y is b_i ($0 \leq i < d$);
2. the number of vertices in $V_{i-1}(x)$ adjacent to y is c_i ($0 \leq i < d-1$).

The array $(k, b_0, \dots, b_{d-1}, c_0, \dots, c_{d-1})$ is the intersection array I . From the intersection array, we can determine if a graph is also strongly regular. If it has a diameter of two, then it is a strongly regular graph. Many interesting distance-regular graphs belonging to well-known graph families arise from primitive groups. Using the GAP system, these graphs were systematically studied up to 4095 vertices.

Results

Research was conducted using the GAP software with the GRAPE package. Focus was placed on graphs that arose from primitive permutation groups up to 4095 vertices. The GAP library used for this research only contained the graphs up to this number of vertices. However, due to the run times of some larger ranks, not all graphs of each group in the library were found. To analyze the vast volume of graphs that were outputted, they were categorized based on the number of vertices they contained. The two sections included those with a prime or prime power number of vertices and those that were composite.

Various properties of the graphs were collected using built-in commands on the GAP software. These included the group, combination of orbits (number of orbits, on ordered pairs) that give a distance-regular graph, rank (number of orbits), and intersection array. Based on this information, we could conclude the specific graph and its family from the available literature.

Unknown Graph and NO₂(2) Graph

When attempting to identify a graph that was found on 136 vertices, we were unable to find anything about it in the literature. There was another graph NO₂(2) on 136 vertices that shared the same intersection array, so we investigated further to determine the similarities between the two graphs. This was done by comparing the strongly regular array, group, rank, clique number, and the chromatic number of both graphs and their complements. The following table outlines the findings.

Graph	Johnson	Complement	NO ₂ (2)	Complement
Intersection Array	{63, 21, 28}	{72, 31, 40}	{63, 21, 28}	{72, 31, 40}
Strongly Regular Array	{136, 63, 30, 28}	{136, 72, 36, 40}	{136, 63, 30, 28}	{136, 72, 36, 40}
Group	PSU(2,17)	PSU(2,17)	PSO(8,2)	PSO(8,2)
Rank	12	12	3	3
Clique Number	8	10	8	7
Chromatic Number	15	17 or 18	20	17

This information was found using the GAP software. Due to the long run times of obtaining the chromatic number of graphs, we were unable to determine the exact value of the complement of the unknown graph and NO₂(2). We did find a possible range; however, Gordon Rowe determined that the chromatic number of NO₂(2) was 20 using a different approach and also narrowed down the chromatic number of the complement of the unknown graph to 17 or 18.

Summary

- To conduct research on distance-regular graphs arising from primitive groups, the GAP system was used, along with the GRAPE package, to look at graphs on up to 4095 vertices.
- Hundreds of graphs were obtained, and many of these graphs fit into well-known graph families such as the Hamming, Johnson, Kneser, and Paley graphs. We also found many sporadic graphs, including the Sylvester graph, Biggs-Smith graph, Suzuki graph, and the Rubikoff graph.
- During our research, we came across a graph on 136 vertices that we determined to be unknown. This graph has the same parameters as another graph on 136 vertices, the NO₂(2) graph.
- Extra information was collected on both the unknown graph and the NO₂(2) graph, along with their complements, and it was determined that these graphs have notable differences.

Figure 1: Hamming H(2,3) Graph

Figure 2: Petersen Graph P(5,2)

Figure 3: Johnson Graph J(5,2)

Paley Graphs

- The Paley graphs exist when the number of vertices is a prime or prime power.
- The Paley graphs found were on the number of vertices including the prime squares from 3 to 61 and the prime powers $12^2, 5^2, 7^2, 11^2, 13^2$.
- The Paley graphs have the intersection array $I = \left(\frac{q-1}{2}, \frac{q-1}{2}, \frac{q-1}{2} \right)$.
- They also are strongly regular with the parameters $(n, k, \lambda, \mu) = \left(q, \frac{q-1}{2}, \frac{q-5}{4}, \frac{q-1}{4} \right)$.

Sporadic Graphs

- There were more than 100 sporadic graphs that we found that did not fit into any known families. Some notable sporadic graphs are the Sylvester graph, Biggs-Smith graph, Suzuki graph, and the Rubikoff graph.
- The Sylvester graph is on 36 vertices, arising from $PSU(2,9)$, with intersection array $(4, 2, 1, 1, 4)$.
 - The Biggs-Smith graph is on 102 vertices, arising from $PSU(2,17)$ with intersection array $(1, 2, 2, 1, 1, 1, 1, 1, 1, 1, 2)$.
 - The Suzuki graph is on 1782 vertices, arising from Suz_2 with intersection array $(146, 315, 1, 96)$.
 - The Rubikoff graph is on 4060 vertices, arising from the group Bu_6 with intersection array $(175, 803, 1, 70)$.

Positivity is undecidable in tensor product of free algebras

- Yuming Zhao (University of Waterloo)

Positivity and Sum-of-squares
A polynomial $f \in \mathbb{R}[x_1, \dots, x_n]$ is said to be **positive** if $f(\vec{x}) \geq 0$ for all $\vec{x} \in \mathbb{R}^n$. Hilbert's 17th problem concerns whether every positive polynomial can be expressed as a sum of squares of other polynomials $\sum_{i=1}^k p_i^2$.

Main results
Theorem
Let \mathcal{A} be one of the algebras $\mathbb{Q}^*(x_1, \dots, x_n)$ or $\mathbb{Q}\langle F_n \rangle$. If n is large enough, then the decision problem
Given $\alpha \in \mathcal{A} \otimes_{\mathbb{Q}} \mathcal{A}$, is α positive as an element of $\mathcal{A}_{\mathbb{C}} \otimes_{\mathbb{C}} \mathcal{A}_{\mathbb{C}}$?
is undecidable (coRE-hard).

Corollary
Sum-of-squares is NOT a necessary condition for positivity in tensor product of free algebras.

Key ideas
Fix a universal Turing machine M . We construct a computable map $\alpha: \mathbb{N} \rightarrow \mathbb{Q}\langle F_n \rangle \otimes_{\mathbb{Q}} \mathbb{Q}\langle F_n \rangle$ such that
 $\alpha(m)$ is positive $\iff M$ does not halt on the input m .
To achieve this, we need to encode the halting problem for the Turing machine M into a finitely-presented group.
We can first encode the halting problem for M in a **recursively-presented group**.
 $(\infty \text{ generators} | \infty \text{ relations})$
 \downarrow HNN extensions
 $(\text{finite generators} | \infty \text{ relations})$
 \downarrow efficient Higman's embedding [4]
 $(\text{finite generators} | \text{finite relations})$

Motivations from quantum information
In quantum information theory, we are interested in the tensor product algebras $\mathbb{C}P_n \otimes \mathbb{C}P_m$ and $\mathbb{C}P_n^* \otimes \mathbb{C}P_m^*$ which models a physical system with two spatially separated subsystems.
In each subsystem we can make n different quantum measurements, each with m outcomes.

Undecidability
- RE: recursively enumerable. $\mathcal{L} = \mathcal{L}_{\text{yes}} \cup \mathcal{L}_{\text{no}}$ is in RE if
- \exists an algorithm M accepts $x \in \mathcal{L}_{\text{yes}}$ in finite steps;
- M may not halt for $x \in \mathcal{L}_{\text{no}}$
- coRE: the complement of RE
 $x \mapsto M$ halts on x ? \rightarrow YES The halting problem for a universal Turing machine M is undecidable (RE-complete)

Series expansion via unwinding

- William Verreault (Université Laval)

Series expansion via unwinding

William Verreault (william.verreault.2@ulaval.ca)
Université Laval

The Context

Function Expansion Theory has profound applications in all areas of science, especially in Signal Processing, Physics, and Engineering.

- An entire function has the **Taylor series expansion** $f(z) = \sum_{n=0}^{\infty} a_n z^n$, which converges for all values of z in \mathbb{C} .
- A 2π -periodic function has the **Fourier series expansion** $f(z) = \sum_{n=-\infty}^{\infty} f_n e^{in z}$. In particular, it converges in $L^2(\mathbb{T}) \iff f \in L^2(\mathbb{T})$.

New interpretation of Taylor series: $f(z) = f(0)$ has a neat trick so we can write $f(z) = f(0) + z f'(0) + \frac{z^2}{2!} f''(0) + \dots$ for some holomorphic f . This gives a procedure for a naive unwinding series:

$$\begin{aligned} f(z) &= f(0) + (f(z) - f(0)) \\ &= f(0) + z f_1(z) \\ &= f(0) + z f_1(0) + z^2 f_2(z) \\ &\dots \\ &= f(0) + z f_1(0) + z^2 f_2(0) + z^3 f_3(0) + \dots \end{aligned}$$

Can this observation be pushed further?

Blaschke Unwinding

In 1995, R. Colman had the revolutionary idea of interpreting the monomials $z \mapsto z^n$ as finite Blaschke products, and thus suggested to develop $f(z)$ as $f(z) = c_0 + c_1 B_1(z) + c_2 B_2(z) + \dots$, where c_n are constants and B_n are finite Blaschke products.

Definition. For $a_j \in \mathbb{D}$ and $\gamma \in \mathbb{T}$, a **finite Blaschke product** is a function of the form

$$B(z) = \gamma \prod_{j=1}^n \frac{z - a_j}{1 - \bar{a}_j z}$$

This relies on the **Blaschke factorization theorem**.

Fig. 1: Blaschke factorization of a holomorphic function.

Explicitly, we obtain the **Blaschke unwinding expansion**

$$f(z) = f(0) + c_1 B_1(z) + c_2 B_2(z) + \dots$$

which was first studied by M. Nahon [3] in 2000.

It was also rediscovered and studied under the name **Adaptive Fourier Decomposition**, on which there is a vast literature.

Why Study this Unwinding Series?

Practical interest of the method:

- Convergence at least as fast as Fourier series (exponential rate);
- Blaschke factorization without knowing the roots is computationally fast and stable;
- Stability of the method under small diffeomorphisms of the underlying domain, in contrast to classical Fourier methods;
- Unwinding outperforms frequency extractions via SST time-frequency analysis.

Several **real-world applications** of the unwinding series:

- Speech signals and recognition, medical signal analysis, signal processing for gravitational waves, predicting the stock price movements, etc.

Background

We work in analytic function spaces. Important examples include

- The **Hardy spaces** $H^p(\mathbb{T}) = \{f \in L^p(\mathbb{T}) : \tilde{f}(n) = 0 \text{ for } n \leq -1\}$, with H^∞ the set of bounded analytic functions on \mathbb{D} with sup norm;
- Reproducing kernel Hilbert spaces (RKHS), Hilbert spaces defined by the fact that pointwise evaluation is a continuous linear functional (e.g., \mathbb{C}^n , H^2 , the Dirichlet space \mathcal{D} , Sobolev spaces H^1).

The **convergence** of the Blaschke unwinding series was a major question from the beginning, but has always been a very delicate issue. Satisfactory results only came in the 2010s.

- Convergence in $H^2(\mathbb{T})$ [4]; general results [2] that imply convergence in L^1 for initial data in \mathcal{D} , and in H^1 for initial data in $H^{1/2}$ ($\mu > -1/2$); convergence of a more general inner-outer unwinding series for functions in $H^1(\mathbb{T})$ [1].

Notation and Setup

Seeing the past developments and using our knowledge of Operator Theory, we considered the more general series expansion

$$f(z) = c_0 + c_1 b_1(z) + c_2 b_2(z) b_1(z) + \dots$$

where b_n are elements of the closed unit ball of the multiplier algebra of our space of analytic functions \mathcal{H} and c_n are some functions.

Monomials $z^n \mapsto$ **Blaschke products** \mapsto **linear functions** \mapsto **Unit ball of $\mathcal{M}(\mathcal{H})$**

Definition. The **Riesz projection** is the orthogonal projection from L^2 onto H^2 .

For example, $P(1 + 2 \cos \theta) = P(e^{-i\theta} + 1 + e^{i\theta}) = 1 + e^{i\theta}$.

Definition. For $\varphi \in L^\infty(\mathbb{T})$ and $f \in H^2(\mathbb{T})$, the **Toeplitz operator** associated to φ is

$$T_\varphi f = P(\varphi f)$$

Note that $\mathcal{M}(H^2) = H^\infty$. For $b \in H^\infty$, we let

$$Q_b = I - T_b P_b$$

A General Unwinding Scheme

For a sequence $\{b_n\}_{n \geq 1}$ of elements of the unit ball of H^∞ , we can unwind $f \in H^2$ using our previous notation as

$$f = Q_0 f = b_1 Q_1 f = b_1 b_2 Q_2 f = b_1 b_2 b_3 Q_3 f + \dots$$

Furthermore, the series converges in H^2 .

In fact, a more abstract result for RKHS (using multiplication operators) and a result for more abstract but more general function spaces also hold.

Hence, we can say that these results are relevant for at least **two principal reasons**:

- Our unwinding generalizes the previously known unwinding schemes and is adapted to the language of Operator Theory.
- We prove convergence in more spaces and in more generality, encompassing all previously known results.

Optimality and Sustainability of Delayed Impulsive Harvesting

- Jenny Lawson (University of Calgary)

Optimality and Sustainability of Delayed Impulsive Harvesting

Jenny Lawson^{1,2} and Elena Braverman¹

¹ Department of Mathematics and Statistics, University of Calgary
² Werklund School of Education, University of Calgary

Motivation

In Fisheries Science, the Maximum Sustainable Yield (MSY) is often used as a guideline for harvesting quotas. It has been used to make fishery management decisions since the mid 20th century and is enshrined in some international law (such as the 1982 United Nations Convention on the Law of the Sea (UNCLOS)) [3].

This was an indication that there was something wrong with how we were estimating sustainable harvests.

One issue was that our methods relied on the assumption that harvesting happened continuously rather than in many short spurts. In 2003, [4] suggested using an impulsive DE to take these short spurts of harvesting into account.

But the positive solution corresponding to the MSY was globally asymptotically stable. This still didn't quite explain what we were observing in fisheries.

What if there was a delay in the information used to make harvesting decisions?

Our models were assuming that data was up to date. Was this a valid assumption? "and the scientific advice was based on the status of the stock two years earlier than the year in which the TAC was being applied" - Resource Projects for Canada's Atlantic Fisheries 1989-1993, Department of Fisheries and Oceans.

Model & Method

Consider a logistic DE subject to impulsive delayed harvesting, where the impulsive deduction is a function of the population size at the time of a previous harvesting event. In the model, k represents the number of harvesting periods T that the information has been delayed by.

$$\begin{cases} \frac{dN}{dt} = rN(t) \left(1 - \frac{N(t)}{K_c}\right), & t \neq nT \\ N(nT^+) = \max\{N(nT) - EN((n-k)T), 0\}, & t = nT \\ N(0^+) = N_0^+, N(0) = N_0, \dots, N((k-1)T) = N_{-(k-1)} \end{cases}$$

Local Asymptotic Stability of Positive Solution

Sustainability of Associated Yield

Instead of directly studying the delayed harvesting model, we can deduce many relevant properties by studying an associated non-linear higher order difference equation. Let $x_n = N(nT^+)$,

$$x_{n+1} = \max \left\{ \frac{K_c x_n e^{rT}}{K_c + x_n (e^{rT} - 1)} - E, \frac{K_c x_{n-k} e^{rT}}{K_c + x_{n-k} (e^{rT} - 1)}, 0 \right\}, \quad n \geq k$$

Results

The yield is maximized when $E = 1 - e^{-rT/2}$.

$$MY = \frac{K_c (e^{rT/2} - 1)}{T (e^{rT/2} + 1)}$$

Psst... this is the same MY as the non-delayed model [4]

Is this yield sustainable? This yield is sustainable if and only if either $k = 1$ or $k \geq 2$ and rT is within the following bounds,

$$0 < rT < f(k) := -2 \ln \left(1 - 2 \cos \left(\frac{\pi k}{2k+1} \right) \right)$$

Results (Cont.)

So, we've found a MSY... Unfortunately, as k increases the range of values where the MY is sustainable gets smaller and smaller.

What if my yield is NOT maximal? Can it then be sustainable? Yes! However, if $rT \geq f(k)$, then there exists $E^* \in (0, 1 - e^{-rT/2})$ such that $E \in (0, E^*)$ for the yield to be sustainable.

One BIG change because of the delay... the solution is not globally attracting for all initial values (unlike the model with no delay). Each dot represents whether the population survives (black) or goes extinct (red) given the initial conditions.

Conclusions

Delays DO matter: The Maximum Yield (MY) is not affected, but whether it is sustainable and becomes a MSY is highly dependent on the delay!

Delays DO matter: solutions are not guaranteed to survive for all positive initial conditions, even when they are asymptotically stable. We can have extinction in finite time!
